LES Inlets

Swirl inlets

Test case I –
cylindrical
pipe

Test case II –
sudden
expansion

Discussion +
Conclusions

Turbulence : need to reduce d.o.f. in problem –

- implement some form of averaging,
- simulate 'mean' flow
- model 'turbulent' fluctuations

RANS – time/ensemble averaged mean flow. All quantities static or slowly varying.

LES – volume averaging via filter

$$u(t) = \bar{u}(t) + u'(t) \quad \text{where} \quad \bar{u}(t) = \int G(x - x') u(x', t) d^3x$$

GS quantities stochastically varying – causes significant problems at inlets

LES Inlets

Swirl inlets

Test case I –
cylindrical
pipe

Test case II –
sudden
expansion

Discussion +
Conclusions

Very important – many flows affected by turbulence at inlet.
LES inlet must contain some stochastic component due to GS turbulence.

Required properties :

- stochastically time-varying
- on scales down to filter scale
- compatible with the N-S equations
- ‘looks’ like turbulence
- specify turbulent properties (length scales, turbulent magnitudes etc.)

Simply adding on random fluctuations does not work.

Standard approaches :

Synthesis Construct pseudo-random field from base functions (e.g Fourier, digital filters etc) and attempt to match required properties.

Library lookup Perform separate calculation to generate turbulence data and map to inlet

OpenFOAM also includes mapping method; sample flow downstream and map back to inlet.

C++ class library for finite volume CFD on arbitrary unstructured grids, developed by H.Weller and H. Jasak (Imperial College, Nabla Ltd, now OpenCFD Ltd, Wikki Ltd and U.Zagreb)

Multi-purpose library with well-validated LES capability using 2nd order schemes, CG solvers, PISO and a range of SGS models (Smag, 1 equation, dynamic models).

Implements LES inlet condition based on internal mapping on main domain

Test case II –
sudden
expansion

Discussion +
Conclusions

We wish to manipulate inlet to specify mean flow profile – eg. swirl – also turbulence profiles.

Swirl particularly important as this is difficult to model with RANS due to streamline curvature effects.

Previous attempts; mean flow plus fluctuations (Huang and Yang 2005, Wang *et al.* 2007), library lookup (Wang and Bai 2005, Schlüter *et al.* 2004) based on cyclic channel with fixed body force (Pierce and Moin 1998).

Our approach; mapping on main domain with appropriate forcing and control algorithms :

- 1 Apply control algorithm to driving body force to generate correct mean (and swirl) profile

$$\bar{\mathbf{F}} = \frac{V_b}{L} [\alpha(\mathbf{v}_{des} - \langle \bar{\mathbf{v}} \rangle) + (\mathbf{v}_{des} - \bar{\mathbf{v}})], \quad (1)$$

- 2 Apply velocity corrections with control algorithm within mapping section

$$\bar{\mathbf{v}}^* = \mathbf{v}_{des} + (\bar{\mathbf{v}} - \langle \bar{\mathbf{v}} \rangle) \times \left(\frac{(R_{des})_{ii}}{R_{ii}} \right)^{1/2}, \quad (2)$$

LES Inlets

Swirl inlets

Test case I –
cylindrical
pipe

Test case II –
sudden
expansion

Discussion +
Conclusions

Swirling flow in a cylindrical pipe length $10D$ (pipe diameter $D = 2$ m)

Mesh resolution 448 cells across section, 30 cells/metre of length.

Swirl S defined

$$S = \frac{1}{R_0} \frac{\int_0^{R_0} r^2 \langle v_z \rangle \langle v_\theta \rangle dr}{\int_0^{R_0} r \langle v_z \rangle^2 dr} \quad (3)$$

here, $S = 0.6$ at $Re = 30,000$.

Case run for 4000 s – 60 transits through domain

Target profile from averaged LES on short cyclic domain.

Test case; sudden expansion jet flow with/without swirl

Measurements in Turbulent Swirling Flow through an Abrupt Axisymmetric Expansion. Dellenback, Metzger, Neitzel. *AIAA.J.* **26#6** (1988)

Experimental data for $Re = 30,000$, $S = 0, 0.6$. $S > 0.25$ creates central recirculation, vortex breakdown – turbulence production within domain. Still need to generate correct inlet conditions.

1.5 million cells; $y^+ = 16$ upstream of expansion.

Compare with experimental and literature LES (Schlüter *et al.*)

LES Inlets

Swirl inlets

Test case I –
cylindrical
pipe

Test case II –
sudden
expansion

Discussion +
Conclusions

No swirl:

Swirl number 0.6:

Pipe case

- Used to develop methodology – no comparison with reference data
- Turbulence generated at inlet behaves much as expected :
 - Flow field uniform across mapping plane
 - No unphysical behaviour in mapping section or downstream
 - No significant periodicity in solution

Sudden expansion

- Good comparison with experimental and literature LES data; mean flow well reproduced; for all properties results at least as good as lit LES data.
- No need for turbulence to develop (cf. synthesis methods)
- High swirl cases less sensitive to inlet turbulence, but actual bulk swirl needs to be reproduced.

LES Inlets

Swirl inlets

Test case I –
cylindrical
pipe

Test case II –
sudden
expansion

Discussion +
Conclusions

- Mapping method can be adapted using bulk forces, velocity corrections, and feedback control to generate desired mean and turbulent profiles
- Profiles from experimental data or pre-computation (possibly from RANS)
- Method performs better than synthesis methods, at least as well as library methods
- and is more elegant, simpler
